Section 4: Technical Summary and Application Guidelines

INTRODUCTION

Tantalum capacitors are manufactured from a powder of pure tantalum metal. OxiCap® - niobium oxide capacitor is made from niobium oxide NbO powder. The typical particle size is between 2 and 10 μm.

Figure below shows typical powders. Note the very great difference in particle size between the powder CVs/g.

![Tantalum powder](image1.png) ![Niobium Oxide powder](image2.png)

Figure 1a. Tantalum powder

Figure 1b. Niobium Oxide powder

The powder is compressed under high pressure around a Tantalum or Niobium wire (known as the Riser Wire) to form a "pellet". The riser wire is the anode connection to the capacitor.

This is subsequently vacuum sintered at high temperature (typically 1200 - 1800°C) which produces a mechanically strong pellet and drives off any impurities within the powder.

During sintering the powder becomes a sponge like structure with all the particles interconnected in a huge lattice.

This structure is of high mechanical strength and density, but is also highly porous giving a large internal surface area (see Figure 2).

The larger the surface area the larger the capacitance. Thus high CV/g (capacitance voltage product per gram) powders, which have a low average particle size, are used for low voltage, high capacitance parts.

By choosing which powder and sinter temperature is used to produce each capacitance/voltage rating the surface area can be controlled.

The following example uses a 220μF 6V capacitor to illustrate the point.

\[
C = \frac{\varepsilon_r \varepsilon_0 A}{d}
\]

where \(\varepsilon_0\) is the dielectric constant of free space \((8.855 \times 10^{-12} \text{ Farads/m})\)

\(\varepsilon_r\) is the relative dielectric constant

= 27 for Tantalum Pentoxide

= 41 for Niobium Pentoxide

\(d\) is the dielectric thickness in meters

\(C\) is the capacitance in Farads

and \(A\) is the surface area in meters

Rearranging this equation gives:

\[
A = \frac{Cd}{\varepsilon_0 \varepsilon_r}
\]

thus for a 220μF/6V capacitor the surface area is 346 square centimeters, or nearly a half times the size of this page.

The dielectric is then formed over all the Tantalum or niobium oxide surfaces by the electrochemical process of anodization. To activate this, the "pellet" is dipped into a very weak solution of phosphoric acid.

The dielectric thickness is controlled by the voltage applied during the forming process. Initially the power supply is kept in a constant current mode until the correct thickness of dielectric has been reached (that is the voltage reaches the ‘forming voltage’), it then switches to constant voltage mode and the current decays to close to zero.
The chemical equations describing the process are as follows:

**Tantalum Anode:**
\[ 2 \text{Ta} \rightarrow 2 \text{Ta}^{5+} + 10 \text{e}^- \]
\[ 2 \text{Ta}^{5+} + 10 \text{OH}^- \rightarrow \text{Ta}_2\text{O}_5 + 5 \text{H}_2\text{O} \]

**Niobium Oxide Anode:**
\[ 2 \text{NbO} \rightarrow 2 \text{NbO}^{3+} + 6 \text{e}^- \]
\[ 2 \text{NbO}^{3+} + 6 \text{OH}^- \rightarrow \text{Nb}_2\text{O}_5 + 3 \text{H}_2\text{O} \]

**Cathode:**
**Tantalum:**
\[ 10 \text{H}_2\text{O} - 10 \text{e}^- \rightarrow 5\text{H}_2 + 10 \text{OH}^- \]
**Niobium Oxide:**
\[ 6 \text{H}_2\text{O} - 6 \text{e}^- \rightarrow 3\text{H}_2 + 6 \text{OH}^- \]

The oxide forms on the surface of the Tantalum or Niobium Oxide but it also grows into the material. For each unit of oxide two thirds grows out and one third grows in. It is for this reason that there is a limit on the maximum voltage rating of Tantalum & Niobium Oxide capacitors with present technology powders (see Figure 3).

The dielectric operates under high electrical stress. Consider a 220μF 6V part:

- **Formation voltage** = Formation Ratio x Working Voltage
  = 3.5 x 6
  = 21 Volts

**Tantalum:**
- The pentoxide (Ta₂O₅) dielectric grows at a rate of 1.7 x 10⁻⁹ m/V
- Dielectric thickness (d) = 21 x 1.7 x 10⁻⁹
  = 0.036 μm
- Electric Field strength = Working Voltage / d
  = 167 KV/mm

**Niobium Oxide:**
- The niobium oxide (Nb₂O₅) dielectric grows at a rate of 2.4 x 10⁻⁹ m/V
- Dielectric thickness (d) = 21 x 2.4 x 10⁻⁹
  = 0.050 μm
- Electric Field strength = Working Voltage / d
  = 120 KV/mm

The next stage is the production of the cathode plate. This is achieved by pyrolysis of Manganese Nitrate into Manganese Dioxide.

The “pellet” is dipped into an aqueous solution of nitrate and then baked in an oven at approximately 250°C to produce the dioxide coat. The chemical equation is:

\[ \text{Mn} (\text{NO}_3)_2 \rightarrow \text{MnO}_2 + 2\text{NO}_2 \cdot \text{g} \]

This process is repeated several times through varying specific densities of nitrate to build up a thick coat over all internal and external surfaces of the “pellet”, as shown in Figure 4.

The “pellet” is then dipped into graphite and silver to provide a good connection to the Manganese Dioxide cathode plate. Electrical contact is established by deposition of carbon onto the surface of the cathode. The carbon is then coated with a conductive material to facilitate connection to the cathode termination (see Figure 5). Packaging is carried out to meet individual specifications and customer requirements. This manufacturing technique is adhered to for the whole range of AVX Tantalum capacitors, which can be subdivided into four basic groups: Chip / Resin dipped / Rectangular boxed / Axial.

Further information on production of Tantalum Capacitors can be obtained from the technical paper “Basic Tantalum Technology”, by John Gill, available from your local AVX representative.

---

**Figure 4. Manganese Dioxide Layer**

**Figure 5. Cathode Termination**
SECTION 1
ELECTRICAL CHARACTERISTICS AND EXPLANATION OF TERMS

1.1 CAPACITANCE

1.1.1 Rated capacitance ($C_R$).
This is the nominal rated capacitance. For tantalum and OxiCap® capacitors it is measured as the capacitance of the equivalent series circuit at 25°C using a measuring bridge supplied by a 0.5V rms 120Hz sinusoidal signal, free of harmonics with a bias of 2.2Vd.c.

1.1.2 Capacitance tolerance.
This is the permissible variation of the actual value of the capacitance from the rated value. For additional reading, please consult the AVX technical publication “Capacitance Tolerances for Solid Tantalum Capacitors”.

1.1.3 Temperature dependence of capacitance.
The capacitance of a tantalum capacitor varies with temperature. This variation itself is dependent to a small extent on the rated voltage and capacitor size.

1.1.4 Frequency dependence of the capacitance.
The effective capacitance decreases as frequency increases. Beyond 100kHz the capacitance continues to drop until resonance is reached (typically between 0.5 - 5MHz depending on the rating). Beyond the resonant frequency the device becomes inductive.

1.2 VOLTAGE

1.2.1 Rated d.c. voltage ($V_R$).
This is the rated d.c. voltage for continuous operation up to 85°C (up to 40°C for TLJ, TLN, NLJ series).
Operating voltage consists of the sum of DC bias voltage and ripple peak voltage. The peak voltage should not exceed the category voltage. For recommended voltage (application) derating refer to figure 2c of the SECTION 3.

1.2.2 Category voltage ($V_C$).
This is the maximum voltage that may be applied continuously to a capacitor. It is equal to the rated voltage up to +85°C (up to 40°C for TLJ, TLN, NLJ series), beyond which it is subject to a linear derating, to 2/3 $V_R$ at 125°C for tantalum and 2/3 $V_R$ at 105°C for OxiCap®.

1.2.3 Surge voltage ($V_S$).
This is the highest voltage that may be applied to a capacitor for short periods of time in circuits with minimum series resistance of 33Ohms (CECC states 1kΩ). The surge voltage may be applied up to 10 times in an hour for periods of up to 30 seconds at a time. The surge voltage must not be used as a parameter in the design of circuits in which, in the normal course of operation, the capacitor is periodically charged and discharged.

1.2.4 Effect of surges

The solid Tantalum and OxiCap® capacitors have a limited ability to withstand voltage and current surges. This is in common with all other electrolytic capacitors and is due to the fact that they operate under very high electrical stress across the dielectric. For example a 6 volt tantalum capacitor has an Electrical Field of 167 kV/mm when operated at rated voltage. OxiCap® capacitors operate at electrical field significantly less than 167 kV/mm.

It is important to ensure that the voltage across the terminals of the capacitor never exceeds the specified surge voltage rating.

Solid tantalum capacitors and OxiCap® have a self healing ability provided by the Manganese Dioxide semiconducting layer used as the negative plate. However, this is limited in low impedance applications. In the case of low impedance circuits, the capacitor is likely to be stressed by current surges.

Derating the capacitor increases the reliability of the component. (See Figure 2b page 265). The "AVX Recommended Derating Table" (page 267) summarizes voltage rating for use on common voltage rails, in low impedance applications for both Tantalum and OxiCap® capacitors.

In circuits which undergo rapid charge or discharge a protective resistor of 10/V is recommended. If this is impossible, a derating factor of up to 70% should be used on tantalum capacitors. OxiCap® capacitors can be used with derating of 20% minimum.

In such situations a higher voltage may be needed than is available as a single capacitor. A series combination should be used to increase the working voltage of the equivalent capacitor: For example, two 22μF 25V parts in series is equivalent to one 11μF 50V part. For further details refer to J.A. Gill’s paper "Investigation into the Effects of Connecting Tantalum Capacitors in Series", available from AVX offices worldwide.

NOTE:
While testing a circuit (e.g. at ICT or functional) it is likely that the capacitors will be subjected to large voltage and current transients, which will not be seen in normal use. These conditions should be borne in mind when considering the capacitor’s rated voltage for use. These can be controlled by ensuring a correct test resistance is used.

1.2.5 Reverse voltage and Non-Polar operation.

The values quoted are the maximum levels of reverse voltage which should appear on the capacitors at any time. These limits are based on the assumption that the capacitors are polarized in the correct direction for the majority of their working life. They are intended to cover short term reversals of polarity such as those occurring during switching transients of during a minor portion of an impressed waveform. Continuous application of reverse voltage without normal polarization will result in a degradation of leakage current. In conditions under which continuous application of a reverse voltage could occur two similar capacitors should be used in a back-to-back configuration with the negative terminations connected together. Under most conditions this combination will have a capacitance one half of the nominal capacitance of either capacitor. Under conditions of isolated pulses or during the first few cycles, the capacitance may approach the full nominal value. The reverse voltage ratings are designed to cover exceptional conditions of small level excursions into incorrect polarity. The values quoted are not intended to cover continuous reverse operation.

The peak reverse voltage applied to the capacitor must not exceed:

- 10% of the rated d.c. working voltage to a maximum of 1.0v at 25℃
- 3% of the rated d.c. working voltage to a maximum of 0.5v at 85℃
- 1% of the rated d.c. working voltage to a maximum of 0.1v at 125℃ (0.1v at 150℃ THJ Series)

Note: Capacitance and DF values of OxiCap® may exceed specification limits under these conditions.

1.2.6 Superimposed A.C. Voltage (Vr.m.s.) - Ripple Voltage.

This is the maximum r.m.s. alternating voltage; superimposed on a d.c. voltage, that may be applied to a capacitor. The sum of the d.c. voltage and peak value of the superimposed a.c. voltage must not exceed the category voltage, v.c.

Full details are given in Section 2.

1.2.7 Forming voltage.

This is the voltage at which the anode oxide is formed. The thickness of this oxide layer is proportional to the formation voltage for a capacitor and is a factor in setting the rated voltage.
1.3 DISSIPATION FACTOR AND TANGENT OF LOSS ANGLE (TAN D)

1.3.1 Dissipation factor (D.F.).
Dissipation factor is the measurement of the tangent of the loss angle (tan δ) expressed as a percentage. The measurement of DF is carried out using a measuring bridge that supplies a 0.5V rms 120Hz sinusoidal signal, free of harmonics with a bias of 2.2Vdc. The value of DF is temperature and frequency dependent.

Note: For surface mounted products the maximum allowed DF values are indicated in the ratings table and it is important to note that these are the limits met by the component AFTER soldering onto the substrate.

1.3.2 Tangent of Loss Angle (tan δ).
This is a measurement of the energy loss in the capacitor. It is expressed as tan δ and is the power loss of the capacitor divided by its reactive power at a sinusoidal voltage of specified frequency. Terms also used are power factor, loss factor and dielectric loss. Cos (90 - δ) is the true power factor. The measurement of tan δ is carried out using a measuring bridge that supplies a 0.5V rms 120Hz sinusoidal signal, free of harmonics with a bias of 2.2Vdc.

1.3.3 Frequency dependence of Dissipation Factor.
Dissipation Factor increases with frequency as shown in the typical curves that are for tantalum and OxiCap® capacitors identical:

![Typical DF vs Frequency](image1)

1.3.4 Temperature dependence of Dissipation Factor.
Dissipation factor varies with temperature as the typical curves show. These plots are identical for both Tantalum and OxiCap® capacitors. For maximum limits please refer to ratings tables.

![Typical DF vs Temperature](image2)

1.4 IMPEDANCE, (Z) AND EQUIVALENT SERIES RESISTANCE (ESR)

1.4.1 Impedance, Z.
This is the ratio of voltage to current at a specified frequency. Three factors contribute to the impedance of a Tantalum capacitor; the resistance of the semiconductor layer; the capacitance value and the inductance of the electrodes and leads.

At high frequencies the inductance of the leads becomes a limiting factor. The temperature and frequency behavior of these three factors of impedance determine the behavior of the impedance Z. The impedance is measured at 25°C and 100kHz.

1.4.2 Equivalent Series Resistance, ESR.
Resistance losses occur in all practical forms of capacitors. These are made up from several different mechanisms, including resistance in components and contacts, viscous forces within the dielectric and defects producing bypass current paths. To express the effect of these losses they are considered as the ESR of the capacitor. The ESR is frequency dependent and can be found by using the relationship;

\[
ESR = \frac{\tan \delta}{2\pi f C}
\]

Where f is the frequency in Hz, and C is the capacitance in farads.

The ESR is measured at 25°C and 100kHz.

ESR is one of the contributing factors to impedance, and at high frequencies (100kHz and above) it becomes the dominant factor. Thus ESR and impedance become almost identical, impedance being only marginally higher.

1.4.3 Frequency dependence of Impedance and ESR.
ESR and Impedance both increase with decreasing frequency. At lower frequencies the values diverge as the extra contributions to impedance (due to the reactance of the capacitor) become more significant. Beyond 1MHz (and beyond the resonant point of the capacitor) impedance again increases due to the inductance of the capacitor. Typical ESR and Impedance values are similar for both tantalum and niobium oxide materials and thus the same charts are valid for both Tantalum and OxiCap® capacitors.

![Typical ESR vs Frequency](image3)

Technical Summary and Application Guidelines
1.4.4 Temperature dependence of the Impedance and ESR.

At 100kHz, impedance and ESR behave identically and decrease with increasing temperature as the typical curves show.

1.5 D.C. LEAKAGE CURRENT

1.5.1 Leakage current.

The leakage current is dependent on the voltage applied, the elapsed time since the voltage was applied and the component temperature. It is measured at +20°C with the rated voltage applied. A protective resistance of 1000Ω is connected in series with the capacitor in the measuring circuit. Three to five minutes after application of the rated voltage the leakage current must not exceed the maximum values indicated in the ratings table. Leakage current is referenced as DCL (for Direct Current Leakage). The default maximum limit for DCL Current is given by DCL = 0.01CV, where DCL is in microamperes, and C is the capacitance rating in microfarads, and V is the voltage rating in volts. DCL of tantalum capacitors vary within range of 0.01 - 0.1CV or 0.5μA (whichever is the greater). And 0.02 - 0.1CV or 1.0μA (whichever is the greater) for OxiCap® capacitors.

Reforming of Tantalum or OxiCap® capacitors is unnecessary even after prolonged storage periods without the application of voltage.

1.5.2 Temperature dependence of the leakage current.

The leakage current increases with higher temperatures; typical values are shown in the graph. For operation between 85°C and 125°C, the maximum working voltage must be derated and can be found from the following formula.

\[ V_{\text{max}} = \left( \frac{1}{125} \times (T - 85) \right) \times V_R \]

where T is the required operating temperature.

LEAKAGE CURRENT vs. TEMPERATURE

1.5.3 Voltage dependence of the leakage current.

The leakage current drops rapidly below the value corresponding to the rated voltage \( V_R \) when reduced voltages are applied. The effect of voltage derating on the leakage current is shown in the graph. This will also give a significant increase in the reliability for any application. See Section 3.1 (page 265) for details.

LEAKAGE CURRENT vs. RATED VOLTAGE

For input condition of fixed application voltage and including median curve of the Leakage current vs. Rated voltage graph displayed above we can evaluate following curve.
1.5.4 Ripple current.
The maximum ripple current allowed is derived from the power
dissipation limits for a given temperature rise above ambient
temperature (please refer to Section 2, pages 262-263).

1.6 SELF INDUCTANCE (ESL)
The self-inductance value (ESL) can be important for
resonance frequency evaluation. See figure below typical ESL
values per case size.

We can identify the range of \( \frac{V_A}{V_R} \) (derating) values with min-
imum actual DCL as the “optimal” range. Therefore the min-
imum DCL is obtained when capacitor is used at 25 to 40 %
of rated voltage - when the rated voltage of the capacitor is
2.5 to 4 times higher than actual application voltage.

For additional information on Leakage Current, please con-
sult the AVX technical publication “Analysis of Solid Tantalum
Capacitor Leakage Current” by R. W. Franklin.
2.1 RIPPLE RATINGS (A.C.)

In an a.c. application heat is generated within the capacitor by both the a.c. component of the signal (which will depend upon the signal form, amplitude and frequency), and by the d.c. leakage. For practical purposes the second factor is insignificant. The actual power dissipated in the capacitor is calculated using the formula:

\[ P = I^2 R \]

and rearranged to \[ I = \sqrt{\frac{P}{R}} \]  \(\text{Eq. 1}\)

where
- \( I \) = rms ripple current, amperes
- \( R \) = equivalent series resistance, ohms
- \( U \) = rms ripple voltage, volts
- \( P \) = power dissipated, watts
- \( Z \) = impedance, ohms, at frequency under consideration

Maximum a.c. ripple voltage \((U_{\text{max}})\).

From the Ohms’ law equation:

\[ U_{\text{max}} = I R \]  \(\text{Eq. 2}\)

\[ \text{Where } P \text{ is the maximum permissible power dissipated as listed for the product under consideration (see tables). However care must be taken to ensure that:} \]

1. The d.c. working voltage of the capacitor must not be exceeded by the sum of the positive peak of the applied a.c. voltage and the d.c. bias voltage.

2. The sum of the applied d.c. bias voltage and the negative peak of the a.c. voltage must not allow a voltage reversal in excess of the “Reverse Voltage”.

**Historical ripple calculations.**

Previous ripple current and voltage values were calculated using an empirically derived power dissipation required to give a 10°C (30°C for polymer) rise of the capacitors body temperature from room temperature, usually in free air. These values are shown in Table I. Equation 1 then allows the maximum ripple current to be established, and Equation 2, the maximum ripple voltage. But as has been shown in the AVX article on thermal management by I. Salisbury, the thermal conductivity of a Tantalum chip capacitor varies considerably depending upon how it is mounted.

</table>
A piece of equipment was designed which would pass sine and square wave currents of varying amplitudes through a biased capacitor. The temperature rise seen on the body for the capacitor was then measured using an infra-red probe. This ensured that there was no heat loss through any thermocouple attached to the capacitor’s surface.

Results for the C, D and E case sizes

Several capacitors were tested and the combined results are shown above. All these capacitors were measured on FR4 board, with no other heat sinking. The ripple was supplied at various frequencies from 1kHz to 1MHz.

As can be seen in the figure above, the average $P_{\text{max}}$ value for the C case capacitors was 0.11 Watts. This is the same as that quoted in Table I.

The D case capacitors gave an average $P_{\text{max}}$ value 0.125 Watts. This is lower than the value quoted in the Table I by 0.025 Watts. The E case capacitors gave an average $P_{\text{max}}$ of 0.200 Watts that was much higher than the 0.165 Watts from Table I.

If a typical capacitor’s ESR with frequency is considered, e.g. figure below, it can be seen that there is variation. Thus for a set ripple current, the amount of power to be dissipated by the capacitor will vary with frequency. This is clearly shown in figure in top of next column, which shows that the surface temperature of the unit raises less for a given value of ripple current at 1MHz than at 100kHz.

The graph below shows a typical ESR variation with frequency. Typical ripple current versus temperature rise for 100kHz and 1MHz sine wave inputs.

If $I^2R$ is then plotted it can be seen that the two lines are in fact coincident, as shown in figure below.

**Example**

A Tantalum capacitor is being used in a filtering application, where it will be required to handle a 2 Amp peak-to-peak, 200kHz square wave current.

A square wave is the sum of an infinite series of sine waves at all the odd harmonics of the square waves fundamental frequency. The equation which relates is:

$$I_{\text{Square}} = I_p \sin (2\pi f) + I_p \sin (6\pi f) + I_p \sin (10\pi f) + I_p \sin (14\pi f) + \ldots$$

Thus the special components are:

Let us assume the capacitor is a TAJD686M006

Typical ESR measurements would yield.

Thus the total power dissipation would be 0.069 Watts.

From the D case results shown in figure top of previous column, it can be seen that this power would cause the capacitors surface temperature to rise by about 5°C. For additional information, please refer to the AVX technical publication “Ripple Rating of Tantalum Chip Capacitors” by R.W. Franklin.
2.2 OxiCap® RIPPLE RATING

OxiCap® capacitors showing 20% higher power dissipation allowed compared to tantalum capacitors as a result of twice higher specific heat of niobium oxide compared to Tantalum powders. (Specific heat is related to energy necessary to heat a defined volume of material to a specified temperature.)

2.3 THERMAL MANAGEMENT

The heat generated inside a tantalum capacitor in a.c. operation comes from the power dissipation due to ripple current. It is equal to \( I^2R \), where \( I \) is the rms value of the current at a given frequency, and \( R \) is the ESR at the same frequency with an additional contribution due to the leakage current. The heat will be transferred from the outer surface by conduction. How efficiently it is transferred from this point is dependent on the thermal management of the board.

The power dissipation ratings given in Section 2.1 (page 232) are based on free-air calculations. These ratings can be approached if efficient heat sinking and/or forced cooling is used.

In practice, in a high density assembly with no specific thermal management, the power dissipation required to give a 10°C (30°C for polymer) rise above ambient may be up to a factor of 10 less. In these cases, the actual capacitor temperature should be established (either by thermocouple probe or infra-red scanner) and if it is seen to be above this limit it may be necessary to specify a lower ESR part or a higher voltage rating.

Please contact application engineering for details or contact the AVX technical publication entitled “Thermal Management of Surface Mounted Tantalum Capacitors” by Ian Salisbury.
SECTION 3
RELIABILITY AND CALCULATION OF FAILURE RATE

3.1 STEADY-STATE

Both Tantalum and Niobium Oxide dielectric have essentially no wear out mechanism and in certain circumstances is capable of limited self healing. However, random failures can occur in operation. The failure rate of Tantalum capacitors will decrease with time and not increase as with other electrolytic capacitors and other electronic components.

Figure 1. Tantalum and OxiCap® Reliability Curve

The useful life reliability of the Tantalum and OxiCap® capacitors in steady-state is affected by three factors. The equation from which the failure rate can be calculated is:

\[ F = F_V \times F_T \times F_R \times F_B \]

where

- \( F_V \) is a correction factor due to operating voltage/voltage derating
- \( F_T \) is a correction factor due to operating temperature
- \( F_R \) is a correction factor due to circuit series resistance
- \( F_B \) is the basic failure rate level

**Base failure rate.**

Standard Tantalum conforms to Level M reliability (i.e. 1%/1000 hrs) or better at rated voltage, 85°C and 0.1Ω/volt circuit impedance.

- \( F_B = 1.0\% / 1000 \text{ hours for TAJ, TPS, TPM, TCJ, TCQ, } 
  \text{TCM, TCN, J-CAP}^{\text{TM}}, \text{TAC} \)
- \( 0.5\% / 1000 \text{ hours for TCR, TMJ, TRJ, TRM, THJ, NOJ} \)
- \( 0.2\% / 1000 \text{ hours for NOS and NOM} \)

TLJ, TLN, TLC and NLJ series of tantalum capacitors are defined at 0.5 x rated voltage at 85°C due to the temperature derating.

- \( F_B = 0.2\% /1000 \text{ hours at 85°C and } 0.5xV_R \text{ with } 0.10/V \text{ series impedance with 60% confidence level.} \)

**Operating voltage/voltage derating.**

If a capacitor with a higher voltage rating than the maximum line voltage is used, then the operating reliability will be improved. This is known as voltage derating.

The graph, Figure 2a, shows the relationship between voltage derating (the ratio between applied and rated voltage) and the failure rate. The graph gives the correction factor \( F_V \) for any operating voltage.

Figure 2a. Correction factor to failure rate \( F_V \) for voltage derating of a typical component (60% con. level).

The graph, Figure 2b, gives our recommendation for voltage derating for tantalum capacitors to be used in typical applications.

Figure 2b. Gives our recommendation for voltage derating for tantalum capacitors to be used in typical applications.

The graph, Figure 2c, gives voltage derating recommendations for tantalum capacitors as a function of circuit impedance.

Figure 2c. Gives voltage derating recommendations for tantalum capacitors as a function of circuit impedance.
**Technical Summary and Application Guidelines**

**Operating Temperature.**
If the operating temperature is below the rated temperature for the capacitor then the operating reliability will be improved as shown in Figure 3. This graph gives a correction factor $F_T$ for any temperature of operation.

![Figure 3: Correction factor to failure rate $F_R$ for ambient temperature $T$ for typical component (60% con. level).](image)

**Circuit Impedance.**
All solid Tantalum and/or niobium oxide capacitors require current limiting resistance to protect the dielectric from surges. A series resistor is recommended for this purpose. A lower circuit impedance may cause an increase in failure rate, especially at temperatures higher than 20°C. An inductive low impedance circuit may apply voltage surges to the capacitor and similarly a non-inductive circuit may apply current surges to the capacitor, causing localized over-heating and failure. The recommended impedance is 1 Ω per volt. Where this is not feasible, equivalent voltage derating should be used (See MIL HANDBOOK 217). The graph, Figure 4, shows the correction factor, $F_R$, for increasing series resistance.

![Figure 4. Correction factor to failure rate $F_R$ for series resistance $R$ on basic failure rate $F_B$ for a typical component (60% con. level).](image)

**Example calculation.**
Consider a 12 volt power line. The designer needs about 10μF of capacitance to act as a decoupling capacitor near a video bandwidth amplifier. Thus the circuit impedance will be limited only by the output impedance of the board’s power unit and the track resistance. Let us assume it to be about 2 Ohms minimum, i.e. 0.167 Ohms/Volt. The operating temperature range is -25°C to +85°C. If a 10μF 16 Volt capacitor was designed in the operating failure rate would be as follows.

- $F_T = 1.0 \, @ \, 85°C$
- $F_R = 0.85 \, @ \, 0.167 \, \text{Ohms/Volt}$
- $F_V = 0.08 \, @ \, \text{applied voltage/rated voltage} = 75%$
- $F_B = 1% / 1000 \, \text{hours, basic failure rate level}$

Thus $F = 1.0 \times 0.85 \times 0.08 \times 1 = 0.068% / 1000 \, \text{Hours}$

If the capacitor was changed for a 20 volt capacitor, the operating failure rate will change as shown.

- $F_V = 0.018 \, @ \, \text{applied voltage/rated voltage} = 60%$
- $F = 1.0 \times 0.85 \times 0.018 \times 1 = 0.0153% / 1000 \, \text{Hours}$

**3.2 Dynamic.**
As stated in Section 1.2.4 (page 258), the solid capacitor has a limited ability to withstand voltage and current surges. Such current surges can cause a capacitor to fail. The expected failure rate cannot be calculated by a simple formula as in the case of steady-state reliability. The two parameters under the control of the circuit design engineer known to reduce the incidence of failures are derating and series resistance.

The table below summarizes the results of trials carried out at AVX with a piece of equipment, which has very low series resistance with no voltage derating applied. That is if the capacitor was tested at its rated voltage. It has been tested on tantalum capacitors, however the conclusions are valid for both tantalum and OxiCap® capacitors.

**Results of production scale derating experiment**

<table>
<thead>
<tr>
<th>Capacitance and Voltage</th>
<th>Number of units tested</th>
<th>50% derating applied</th>
<th>No derating applied</th>
</tr>
</thead>
<tbody>
<tr>
<td>47μF 16V</td>
<td>1,547,587</td>
<td>0.03%</td>
<td>1.1%</td>

<td>0.01%</td>
<td>0.5%</td>
</tr>
<tr>
<td>22μF 25V</td>
<td>2,256,258</td>
<td>0.05%</td>
<td>0.3%</td>
</tr>
</tbody>
</table>

As can clearly be seen from the results of this experiment, the more derating applied by the user, the less likely the probability of a surge failure occurring.

It must be remembered that these results were derived from a highly accelerated surge test machine, and failure rates in the low ppm are more likely with the end customer.

A commonly held misconception is that the leakage current of a Tantalum capacitor can predict the number of failures which will be seen on a surge screen. This can be disproved by the results of an experiment carried out at AVX on 47μF...
Technical Summary and Application Guidelines

10V surface mount capacitors with different leakage currents. The results are summarized in the table below.

**Leakage current vs number of surge failures.**

Again, it must be remembered that these results were derived from a highly accelerated surge test machine, and failure rates in the low ppm are more likely with the end customer.

<table>
<thead>

</tbody>
</table>

OxiCap® capacitor is less sensitive to an overloading stress compared to Tantalum and so a 20% minimum derating is recommended. It may be necessary in extreme low impedance circuits of high transient or ‘switch-on’ currents to derate the voltage further. Hence in general a lower voltage OxiCap® part number can be placed on a higher rail voltage compared to the tantalum capacitor – see table below.

**AVX recommended derating table.**

</tbody>
</table>

For further details on surge in Tantalum capacitors refer to J.A. Gill’s paper “Surge in Solid Tantalum Capacitors”, available from AVX offices worldwide.

An added bonus of increasing the derating applied in a circuit, to improve the ability of the capacitor to withstand surge conditions, is that the steady-state reliability is improved by up to an order. Consider the example of a 6.3 volt capacitor being used on a 5 volt rail.

The steady-state reliability of a Tantalum capacitor is affected by three parameters; temperature, series resistance and voltage derating. Assume 40°C operation and 0.1 Ohms/Volt series resistance.

The capacitors reliability will therefore be:

\[
\text{Failure rate} = F_U \times F_T \times F_R \times 1\%/1000 \text{ hours}
\]

\[
= 0.15 \times 0.1 \times 1 \times 1\%/1000 \text{ hours}
\]

\[
= 0.015\%/1000 \text{ hours}
\]

If a 10 volt capacitor was used instead, the new scaling factor would be 0.006, thus the steady-state reliability would be:

\[
\text{Failure rate} = F_U \times F_T \times F_R \times 1\%/1000 \text{ hours}
\]

\[
= 0.006 \times 0.1 \times 1 \times 1\%/1000 \text{ hours}
\]

\[
= 6 \times 10^{-4} \%/1000 \text{ hours}
\]

So there is an order improvement in the capacitors steady-state reliability.
SECTION 4
RECOMMENDED SOLDERING CONDITIONS

Both Tantalum and OxiCap® are lead-free system compatible components, meeting requirements of J-STD-020 standard. The maximum conditions with care: Max. Peak Temperature: 260ºC for maximum 10s, 3 reflow cycles. 2 cycles are allowed for F-series capacitors.

Small parametric shifts may be noted immediately after reflow, components should be allowed to stabilize at room temperature prior to electrical testing.

RECOMMENDED REFLOW PROFILE

**Lead-free soldering:**
Pre-heating: 150±15°C/60–120sec.
Max. Peak Temperature: 245±5°C
Max. Peak Temperature Gradient: 2.5ºC/sec.
Max. Time above 230ºC: 40sec. max.

**SnPb soldering:**
Pre-heating: 150±15°C/60–90sec.
Max. Peak Temperature: 220±5°C
Max. Peak Temperature Gradient: 2ºC/sec.
Max. Time above solder melting point: 60sec.

RECOMMENDED WAVE SOLDERING

**Lead-free soldering:**
Pre-heating: 50-165°C/90-120sec.
Max. Peak Temperature: 250-260°C
Time of wave: 3-5sec.(max. 10sec.)

**SnPb soldering:**
Pre-heating: 50-165°C/90-120sec.
Max. Peak Temperature: 240-250°C
Time of wave: 3-5sec.(max.10sec.)

The upper side temperature of the board should not exceed +150°C.

GENERAL LEAD-FREE NOTES

The following should be noted by customers changing from lead based systems to the new lead free pastes.

a) The visual standards used for evaluation of solder joints will need to be modified as lead-free joints are not as bright as with tin-lead pastes and the fillet may not be as large.

b) Resin color may darken slightly due to the increase in temperature required for the new pastes.

c) Lead-free solder pastes do not allow the same self alignment as lead containing systems. Standard mounting pads are acceptable, but machine set up may need to be modified.

Note: TCJ, TCM, TCN, J-CAP™, TCQ, TCR, F38, TLN and F98 series are not dedicated to wave soldering.

RECOMMENDED HAND SOLDERING

Recommended hand soldering condition:

<table>
<thead>
<tr>
<th>Tip Diameter</th>
<th>Selected to fit Application</th>
</tr>
</thead>
<tbody>
<tr>
<td>Max. Tip Temperature</td>
<td>+370°C</td>
</tr>
<tr>
<td>Max. Exposure Time</td>
<td>3s</td>
</tr>
<tr>
<td>Anti-static Protection</td>
<td>Non required</td>
</tr>
</tbody>
</table>

Note: TCJ, TCM, TCN, J-CAP™, TCQ, TCR, F38, TLN and F98 series are not dedicated to hand soldering.
5.1 Basic Materials

Two basic materials are used for termination leads: Nilo 42 (Fe58Ni42) and copper. Copper lead frame is mainly used for products requiring low ESR performance, while Nilo 42 is used for other products. The actual status of basic material per individual part type can be checked with AVX.

5.2 Termination Finishes – Coatings

Three terminations plating are available. Standard plating material is pure matte tin (Sn). Gold or tin-lead (SnPb) are available upon request with different part number suffix designations.*

5.2.1. Pure matte tin is used as the standard coating material meeting lead-free and RoHS requirements. AVX carefully monitors the latest findings on prevention of whisker formation. Currently used techniques include use of matte tin electrodeposition, nickel barrier underplating and recrystallization of surface by reflow. Terminations are tested for whiskers according to NEMI recommendations and JEDEC standard requirements. Data is available upon request.

5.2.2. Gold Plating is available as a special option* mainly for hybrid assembly using conductive glue.

5.2.3. Tin-lead (90%Sn 10%Pb) electroplated termination finish is available as a special option* upon request.

* Some plating options can be limited to specific part types. Please check availability of special options with AVX.
## SECTION 6
### MECHANICAL AND THERMAL PROPERTIES OF CAPACITORS

#### 6.1 Acceleration
98.1m/s² (10g)

#### 6.2 Vibration Severity
10 to 2000Hz, 0.75mm of 98.1m/s² (10g)

#### 6.3 Shock
Trapezoidal Pulse, 98.1m/s² for 6ms.

#### 6.4 Adhesion to Substrate
IEC 384-3. minimum of 5N.

#### 6.5 Resistance to Substrate Bending
The component has compliant leads which reduces the risk of stress on the capacitor due to substrate bending.

#### 6.6 Soldering Conditions
Dip soldering is permissible provided the solder bath temperature is ≤ 270°C, the solder time < 3 seconds and the circuit board thickness ≥ 1.0mm.

#### 6.7 Installation Instructions
The upper temperature limit (maximum capacitor surface temperature) must not be exceeded even under the most unfavorable conditions when the capacitor is installed. This must be considered particularly when it is positioned near components which radiate heat strongly (e.g., valves and power transistors). Furthermore, care must be taken, when bending the wires, that the bending forces do not strain the capacitor housing.

#### 6.8 Installation Position
No restriction.

#### 6.9 Soldering Instructions
Fluxes containing acids must not be used.

#### 6.9.1 Guidelines for Surface Mount Footprints
Component footprint and reflow pad design for AVX capacitors.

The component footprint is defined as the maximum board area taken up by the terminators. The footprint dimensions are given by A, B, C and D in the diagram, which corresponds to W1 max., A max., S min. and L max. for the component. The footprint is symmetrical about the center lines.

The dimensions x, y and z should be kept to a minimum to reduce rotational tendencies while allowing for visual inspection of the component and its solder fillet.

Dimensions PS (c for F-series) (Pad Separation) and PW (a for F-series) (Pad Width) are calculated using dimensions x and z.

Dimensions y may vary, depending on whether reflow or wave soldering is to be performed.

For reflow soldering, dimensions PL (b for positive terminal of F-series; b’ for negative terminal of F-series) (Pad Length), PW (a) (Pad Width), and PSL (Pad Set Length) have been calculated. For wave soldering the pad width (PWw) is reduced to less than the termination width to minimize the amount of solder pick up while ensuring that a good joint can be produced. In the case of mounting conformal coated capacitors, excentering (Δc) is needed to except anode tab [a].

Nominal footprint and pad dimensions for each case size are given in the following tables:

### PAD DIMENSIONS: millimeters (inches)

<table>
<thead>
<tr>
<th>Case Size</th>
<th>FSL</th>
<th>PL</th>
<th>PW</th>
<th>PWw</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>4.00 (0.157)</td>
<td>1.40 (0.055)</td>
<td>1.20 (0.047)</td>
<td>0.90 (0.035)</td>
</tr>
<tr>
<td>B</td>
<td>4.00 (0.157)</td>
<td>1.40 (0.055)</td>
<td>1.20 (0.047)</td>
<td>0.90 (0.035)</td>
</tr>
<tr>
<td>C</td>
<td>4.00 (0.157)</td>
<td>1.40 (0.055)</td>
<td>1.20 (0.047)</td>
<td>0.90 (0.035)</td>
</tr>
<tr>
<td>D</td>
<td>4.00 (0.157)</td>
<td>1.40 (0.055)</td>
<td>1.20 (0.047)</td>
<td>0.90 (0.035)</td>
</tr>
</tbody>
</table>

**NOTE:**
These recommendations (also in compliance with EIA) are guidelines only. With care and control, smaller footprints may be considered for reflow soldering.

In the case of mounting conformal coated capacitors, excentering (Δc) is needed to except anode tab [a].

6.10 PCB Cleaning

Ta chip capacitors are compatible with most PCB board cleaning systems. If aqueous cleaning is performed, parts must be allowed to dry prior to test. In the event ultrasonics are used power levels should be less than 10 watts per/litre, and care must be taken to avoid vibrational nodes in the cleaning bath.
